JOB DEMANDS ANALYSIS

Company: City of Burnaby Parks  
Location: Works Yard

Job Title: Labourer – Sewers  
Classification: Regular Duty

Purpose of Activities

The Labourer – Sewers is responsible for performing the labouring duties associated with catch basin installation, sewer line connections, installing storm and sanitary sewer lines, manhole installation and for scoping sewer lines with a television camera and small monitor.

Tools and Equipment

The Labourer - Sewers will use the following tools and equipment to perform his duties:
- Power tools – jack hammer, chain saw, circular pipe saw, fan, hydraulic pump, gas sniffer
- Hand tools – long and short handle shovels, small digging shovel, long bar, chains, sledge hammers, broom, rake, screw drivers and sockets sets for couplers
- Cement mix (25 kg bags), hot cement mix, catch basins, cement rings, grates, manholes and manhole covers, plastic and clay pipe (various diameters and length), television monitor with scope, couplers, elbows, Y’s, pipe dope, rags, pipe grease
- Rubber and leather gloves, long pants, hard hat, face shield or safety glasses, ear protection or foam ear plugs, reflective vest, steel toe boots
- First aid kit
- Traffic cones, traffic signs (lane closure, men and equipment working)

Usual Methods

The Labourer – Sewers will ensure that the truck is loaded with all required tools and equipment for the upcoming day. The crew will drive out to the job site and set out traffic signs and cones to notify motorists and the public of their presence in the area. The Sewers crew may close a lane of traffic depending on the location of the work and traffic volume.

Usual Methods (Continued)

After the traffic signs and cones have been placed the Labourers will set out all of the tools and equipment they expect to use during the repair or installation. The tools and equipment are carried to a spot near where the ditch will be dug. The Labourers must wait for the backhoe or excavator to expose the pipe or grade the new trench. As the Labourers wait, they will use brooms and shovels to keep the edges of the ditch clear of any dirt, rocks or debris that may interfere with their work later. The Padman nonverbal and verbal communication to assist the Backhoe Operator with the dig.

Once the Backhoe Operator has proceeded far enough along with the ditch, the Labourers will enter the ditch, either by jumping into a shallow ditch or by using a ladder if the ditch is
deeper. Ditches over one metre deep require the use of a cage(s) to protect the Labourers while they work in the ditch. The cage(s) is lowered into the ditch by the Backhoe. The cage(s) are pulled along the ditch as work proceeds.

One Labourer will stay on the surface and he is responsible for anticipating the tool and equipment needs of the Labourer who is down in the ditch. This Labourer will make the necessary preparations to the pipe and other components on the surface before they are lowered into the ditch for assembly. He will cut pipe, string pip, grease the pipe, mix cement and have all the couplers and connections required for the job ready. As they are needed, he will lower them into the ditch either by hand or by rope.

The Labourer in the ditch is responsible for the making the repair or installation of the pipe or component in the ditch. He will most likely be required to dig dirt, rock and debris away from the connection. He will use a long handled shovel at first and then as the working area becomes more confined a small handled scoop is used to remove the remaining debris from around the connection. The connection may be made on a live storm or sanitary sewer line or the Labourer may elect to “pump around” the connection or tie in. In this instance the Labourers will tie into the line above and below to create a bypass.

Once the connection is clear of debris, the Labourer will make the will cut or tie into the line he is working on. A hand or power saw may be used to cut the pipe. The pipes are primarily made of plastic, vitrified clay or they may have been made of an asbestos-clay mix. Ninety-five per cent of existing pipe is plastic. The labourer completes the tie in with a Y and couplers or a straight connection and will tighten the couplers with a screw driver socket. Grease is placed in the bell of the connection and a pipe (up to a four -metre section) is lowered into the ditch. The pipe is roughly fit into the bell opening. The Labourer uses a long bar to push or pull the pipe onto the bell. The step is repeated until pipe is laid the length of the ditch.

In some area catch basins are installed. The catch basin is a large concrete cylinder and grate component that collects storm run off and funnels this water into the storm sewers system. The Backhoe will dig out the area for the catch basin and then lift the catch basin components into position. The Labourers assist with the final installation and tie in to the main line as described above.

The Labourers will also use a television camera and monitor that is fed into the sewer lines to detect problems or check for irregularities.

**Administrative Issues**

The Labourer- Sewers works from Monday to Friday 0700 to 1530 with a ten minute rest period in the morning, a 30 minute lunch break and a ten minute rest period in the afternoon. The Labourer – Sewers is part of a crew that includes a Foreman, Padman, Truck Driver and a Backhoe or Excavation Operator. There are usually two Labourers – Sewers on a crew. There are three Sewers crews. One crew is assigned to North Burnaby, one to Central Burnaby and one to South Burnaby. The Labourer – Sewers can be called out 24 hours per day, seven days per week in an emergency and will occasionally work overtime. Overtime can be an extended day or called in during off-hours. The Labourer – Sewers will work on residential streets, lanes and major thoroughfares in the City of Burnaby. In the course of their work the Labourers are required to enter confined spaces where various
gases may be present. They will use a gas sniffer to detect these gases and will only enter the area when it has been deemed safe to do so.

**Activity Demand Variables**

These variables are tasks that must be carried out by the employee and are implicitly or explicitly required as objectives of the job.

- Shovel or dig around sewer pipe and/or utilities (gas, water, sewer, electric) in the ditch
- Climb up and down a ladder into the ditch that can range from one to seven metres deep
- Raise and lower tools and equipment by hand or rope into a ditch that can range form one to seven metres deep
- Lift and carry tools, equipment and sewer parts (pipes, catch basins, grates, manholes, etc.) from the truck to the ditch (usually get truck as close as possible to the ditch or work area)
- Repair or install pipe in a live sewer
- Kneel, crouch, bend, stoop in a ditch while installing or repairing sewers line
- Push and/or pull tools and equipment
- Two ten minute rest periods (one in the morning and one in the afternoon) and a 30 minute lunch break
- Work in all weather conditions including prolonged periods of rain or heat
- Enter confined spaces that may contain sewer gases

**Worker Decision Variables**

These variables are the sub-routines and cognitive/physical decisions made by the worker in carrying out the objectives of the job.

- Use machine (backhoe, excavator) to lift and place heavy tools, equipment and parts
- Maintain a minimum level of fitness away from work that will provide an adequate fitness level (aerobic, anaerobic, range of motion, muscular strength and muscular endurance) to perform this job safely and effectively

**Accommodative Considerations**

1. People with injuries to the spine, in any region, may have difficulty with the static and dynamic movements required during the labouring duties of this position.
2. People with shoulder injuries such as rotator cuff tendonitis, bursitis and instability may have difficulty with dynamic and static loading and reaching activities required install and repair sewers, catch basins, etc.
3. People with forearm and elbow injuries such as tennis elbow may have difficulty with the repeated jarring and the static grip forces required to shovel, dig and power tool use including the jackhammer.
4. People with nerve compression injuries in the upper extremities may have difficulty with the repeated and prolonged use hand and power tools (compression and vibration).

Prepared By: Jeffrey J. McGinn, Kinesiologist February 10, 1999
Summary of Stresses

Metabolic Stresses

The aerobic energy systems will be the major source of energy requirement while performing the duties and responsibilities of the Labourer - Sewers. This energy system will be utilized during the repair and installation of storm drains, sanitary mains, catch basins, manholes and scoping sewer lines with the video camera. The anaerobic energy systems may be required to supply energy for brief intense periods of work, which may include heavy or sustained lifting or carrying; or towards the end of the day when the aerobic energy system has been depleted. In this last instance the anaerobic energy system becomes the primary energy source.

Structural Stresses

Spine – Significant loading of the spinal structures are likely in this position. Prolonged loaded and unloaded forward flexion, extension, lateral flexion and rotation of the spine are all movements required by the Sewers Labourer. Forward flexed postures require no activity from the torso musculature, but increase asymmetrical disc compression and passive stretch on the posterior spinal ligaments and disc fibres. This can contribute to disc integrity problems as well as contributing to deconditioning of the torso support musculature. Lateral flexion and/or rotation with or without forward flexion (loaded or unloaded) will significantly increase the shear forces encountered by the discs, fibres and spinal ligaments. The Sewers Labourer will handle loads from less than one to 82 kilograms.

Neck, Shoulders and Upper Extremity – the Sewers Labourer will often perform prolonged and repeated static and dynamic movements. These static and dynamic movements through the shoulder and upper extremity require the rotator cuff muscle groups, upper trapezius and scalene muscles of the neck to maintain a significant load. Static loading of the of the forearm flexors, extensors, supinator, pronator teres and the pronator quadratus during tool use (shovel, hand and power tools, etc) will increase the risk of injury to these areas. Power and air tool use (saws, jackhammers, etc) will also increase the vibration, jarring and compressive forces from the grip to the elbow and shoulder that may lead to over use tendon or nerve injuries.

Hips and Lower Extremities – Standing and walking on concrete and asphalt for the entire shift increase the compressive forces through the ankles, knee, hips and spine. The awkward positions required to access pipe and component parts do not allow the Sewers Labourer to perform the required work from a stable base of support. This in turn will increase the risk of injury for all of the other structures.

INTERVENTIONS

Recommendations that could be implemented to increase productivity and lessen the risk of injury are listed below:

1. Encourage the Sewers Labourer to maintain an increased level of fitness away from work that will focus on cardiovascular endurance, muscular strength, muscular endurance and flexibility.
2. Install a Sidewinder on the back of the Sewer Crews Five-Ton Trucks. The Sidewinder will place gravel into the ditch in a more effective and efficient manner. Presently, the gravel is either dumped (truck or wheelbarrow) into the ditch and moved by shovel to where it is required.

3. Provide knee pads for the Sewers Labourer for any work where kneeling is required, specifically in an open excavation.

4. Provide regular education in effective use of the body and neutral joint positions for this type of work.

5. Encourage the Sewers labourer to ask for assistance (co-worker or backhoe) when handling heavy and/or oversized parts or pieces.
